(Received 9 May 1991; accepted for publication 20 August 1991)

The Dirac equation is solved for an electron in a Kerr–Newman geometry using an adaptation of the procedure of Chandrasekhar. The corresponding eigenfunctions obtained can be represented as series of Jacobi polynomials. The spectrum of eigenvalues can be calculated using continued fraction techniques. Representations for the eigenvalues and eigenfunctions are obtained for various ranges of the parameters appearing in the Kerr–Newman metric. Some comments concerning the bag model of nucleons are made.

I. INTRODUCTION AND DIRAC EQUATION SEPARATION

The Kerr–Newman¹ space-time represents the external gravitational field of a charged rotating black hole. The Kerr space-time² has the remarkable property that many of the equations of mathematical physics are solvable by means of a separation-of-variables-type ansatz.³ This property allows one to study linear gravitational perturbations, for example, in the neighborhood of a Kerr space-time solution. Solutions of Maxwell's equations and the Dirac equation can also be obtained by this method. The separable functions that arise have been studied by a number of authors.^{4–8} In this article, after rederiving the separability of the Dirac equation in the Kerr–Newman space-time background,⁹ we develop new methods for solving the resulting equations. In particular we compute the spectrum of the separation parameter for small values of the parameter a , as well as for large values. Using symmetry properties of the equations in the angular variable θ we reduce the problem to one involving a three-term recurrence relation. This enables the spectrum to be computed in terms of continued fractions. In addition to developing properties of the θ -dependent separation functions we derive a three-term matrix recurrence relation for the separated r -dependent equations. Representations of these solutions for large a and r are then developed. For the particular case of flat space, expansion theorems are given for the r -dependent functions. Finally we comment on the applicability of these functions to bag models of nucleons.

We use consistently the spinor notation of Penrose and Rindler¹⁰ and, in particular, the null tetrad formalism. The Kerr–Newman solution of Einstein's equations has the line element

$$ds^2 = \left(1 - \frac{2Mr}{\rho^2}\right) dt^2 - \rho^2 \left(\frac{dr^2}{\Delta} + d\theta^2\right) - \left((r^2 + a^2) + \frac{2a^2Mr \sin^2 \theta}{\rho^2}\right) \sin^2 \theta d\phi^2 + \frac{4aMr \sin^2 \theta}{\rho^2} dt d\phi, \quad (1.1)$$

where $\Delta = r^2 + a^2 + e^2 - 2Mr$, $\rho^2 = r^2 + a^2 \cos^2 \theta$, and $\bar{\rho} = r + ia \cos \theta$. The electromagnetic field (vector potential) due to the charge of this solution is $(A_r, A_\theta, A_\phi) = (-er/\rho^2, 0, era \sin^2 \theta/\rho^2)$. Specifically, we adopt the Kinnersley null tetrad³ of vectors with components

$$\begin{aligned} l^i &= (1/\sqrt{2}\Delta)(r^2 + a^2, \Delta, 0, a), \\ n^i &= (1/\sqrt{2}\rho^2)(r^2 + a^2, -\Delta, 0, a), \\ m^i &= (1/\sqrt{2}\bar{\rho})(ia \sin \theta, 0, 1, i \operatorname{cosec} \theta), \\ \bar{m}^i &= (1/\sqrt{2}\bar{\rho}^*)(-ia \sin \theta, 0, 1, -i \operatorname{cosec} \theta). \end{aligned} \quad (1.2)$$

In tetrad components the vector potential is

$$\begin{aligned} A_{00'} &= -er/\sqrt{2}\Delta, \\ A_{11'} &= -er/\sqrt{2}\rho^2, \\ A_{01'} &= A_{10'} = 0. \end{aligned} \quad (1.3)$$

The Dirac equation for spin $\frac{1}{2}$ particles in an electromagnetic field is, in spinor form,

$$(\nabla^{B'} - ieA^B_{B'})\varphi_B = (im_e/\sqrt{2})\chi_{B'}, \tag{1.4}$$

$$(\nabla_B - ieA_B^{B'})\chi_{B'} = -(im_e/\sqrt{2})\varphi_B.$$

In terms of the modified field components $\varphi_0 = \phi_0 e^{i(m\varphi + \sigma t)}$, $\bar{\rho}^* \varphi_1 = \phi_1 e^{i(m\varphi + \sigma t)}$, $\chi_{0'} = X_0 e^{i(m\varphi + \sigma t)}$, $\bar{\rho} \chi_{1'} = X_1 e^{i(m\varphi + \sigma t)}$, these equations assume the form

$$\begin{aligned} & -L_{1/2}\phi_0 + (D_0 - ier/\sqrt{2}\Delta)\phi_1 \\ & = -im_e(r - ia \cos \theta)X_0, \\ (\Delta D_{1/2}^\dagger + ier/\sqrt{2})\phi_0 + L_{1/2}^\dagger\phi_1 \\ & = -im_e(r - ia \cos \theta)X_1, \end{aligned} \tag{1.5}$$

$$\begin{aligned} & -L_{1/2}^\dagger X_0 + (D_0 - ier/\sqrt{2}\Delta)X_1 \\ & = im_e(r + ia \cos \theta)\phi_0, \end{aligned}$$

$$(\Delta D_{1/2}^\dagger + ier/\sqrt{2})X_0 + L_{1/2}^\dagger X_1 = im_e(r + ia \cos \theta)\phi_1.$$

These equations can be solved by the usual ansatz

$$\begin{aligned} \phi_0 &= R_{1/2}S_{1/2}, \quad \phi_1 = R_{-1/2}S_{1/2}, \\ X_0 &= -R_{1/2}S_{-1/2}, \quad X_1 = R_{-1/2}S_{-1/2}, \end{aligned} \tag{1.6}$$

to give the coupled equations

$$\begin{aligned} L_{1/2}S_{1/2} &= (\lambda - am_e \cos \theta)S_{-1/2}, \\ L_{1/2}^\dagger S_{-1/2} &= -(\lambda + am_e \cos \theta)S_{1/2}, \\ (D_0 - ier/\sqrt{2}\Delta)R_{-1/2} &= (\lambda + im_e r)R_{1/2}, \\ (\Delta D_{1/2}^\dagger + ier/\sqrt{2})R_{1/2} &= (\lambda - im_e r)R_{-1/2}, \end{aligned} \tag{1.7}$$

where

$$\begin{aligned} L_{1/2} &= \frac{\partial}{\partial \theta} + Q + \frac{1}{2} \cot \theta, \\ L_{1/2}^\dagger &= \frac{\partial}{\partial \theta} - Q + \frac{1}{2} \cot \theta, \\ D_0 &= \frac{\partial}{\partial r} + i\frac{K}{\Delta}, \\ D_{1/2}^\dagger &= \frac{\partial}{\partial r} - \frac{iK}{\Delta} + \frac{(r-M)}{\Delta}, \end{aligned} \tag{1.8}$$

with

$$Q = a\sigma \sin \theta + m \csc \theta, \quad K = (r^2 + a^2)\sigma + am.$$

The first two of these equations are the same coupled equations that are obtained in the case of Kerr space-time (and even flat space $M=0$). The last two equations are generalizations of the r -dependent equations obtained for the electron. The main problem is to determine the eigenvalues λ . Looking for series solutions of the form

$$S_{1/2} = \sum_{r=N}^{\infty} a_r u_{m, -1/2}^r, \tag{1.9}$$

$$S_{-1/2} = \sum_{r=N}^{\infty} b_r u_{m, 1/2}^r,$$

where $u_{m,n}^j$ (Ref. 11) are the matrix elements of the rotation group and $N = \min\{|m|, \frac{1}{2}\}$, we obtain the recurrence formulas

$$\begin{aligned} & \left[-\lambda + \frac{amm_e}{(2r-1)r} \right] b_r + am_e \left[\frac{\sqrt{(r^2 - m^2)(r^2 - \frac{1}{4})}}{(2r-1)r} b_{r-1} + \frac{\sqrt{((r+1)^2 - m^2)(r^2 - \frac{1}{4})}}{(2r+3)(r+1)} b_{r+1} \right] \\ & = -i \left[\left(r + \frac{1}{2} \right) - \frac{ia\sigma(r + \frac{1}{2})}{r(r+1)} \right] a_r + ia\sigma \left[\frac{\sqrt{(r^2 - m^2)(r^2 - \frac{1}{4})}}{r(2r-1)} a_{r-1} + \frac{\sqrt{((r+1)^2 - \frac{1}{4})(r+1)^2 - m^2}}{(r+1)(2r+3)} a_{r+1} \right], \end{aligned} \tag{1.10}$$

$$\begin{aligned} & \left[\lambda - \frac{amm_e}{2r(r+1)} \right] a_r + am_e \left[\frac{\sqrt{(r^2 - m^2)(r^2 - \frac{1}{4})}}{r(2r-1)} a_{r-1} + \frac{\sqrt{((r+1)^2 - m^2)((r+1)^2 - \frac{1}{4})}}{(r+1)(2r+3)} a_{r+1} \right] \\ & = \left[-i \left(r + \frac{1}{2} \right) - \frac{iam(r + \frac{1}{2})}{r(r+1)} \right] b_r - ia\sigma \left[\frac{\sqrt{(r^2 - \frac{1}{4})(r^2 - m^2)}}{r(2r-1)} b_{r-1} - \frac{\sqrt{((r+1)^2 - \frac{1}{4})(r+1)^2 - m^2}}{(r+1)(2r+3)} b_{r+1} \right]. \end{aligned} \tag{1.11}$$

These two relations can be written in the form

$$\alpha_r C_{r-1} + \beta_r C_r + \gamma C_{r+1} = 0, \tag{1.12}$$

where

$$C_r = \begin{bmatrix} a_r \\ b_r \end{bmatrix}.$$

In order to compute the spectrum of λ we could suitably redefine the vector $C_r = \Omega_r D_r$ such that the three-term vector recurrence relation has the form $-\delta_r D_{r-1} + D_r + \epsilon_r D_{r+1} = 0, D_0 + \epsilon_0 D_1 = 0$. The corresponding spectrum for λ can then be calculated from the determinant of the matrix infinite continued fraction:

$$\det(I + \epsilon_0(I + \epsilon_1(I + \epsilon_2(I + \dots \delta_2)^{-1} \delta_1)^{-1}) \delta_0) = 0. \tag{1.13}$$

To obtain a three-term recurrence relation¹² we observe that the equations admit the discrete symmetry obtained by the transformation

$$P: \theta \rightarrow \pi - \theta,$$

$$PS_{1/2}(\theta) = S_{1/2}(\pi - \theta) = \epsilon S_{-1/2}(\theta), \tag{1.14}$$

$$PS_{-1/2}(\theta) = S_{-1/2}(\pi - \theta) = \epsilon S_{1/2}(\theta).$$

Therefore we can impose the symmetry requirements that

$$S_{1/2}(\pi - \theta) = \epsilon S_{-1/2}(\theta), \tag{1.15}$$

$$S_{-1/2}(\pi - \theta) = \epsilon S_{1/2}(\theta),$$

where $\epsilon = \pm 1$.

Using the relation $u_{m,-1/2}^j(-\cos \theta) = (-1)^{j-m} i u_{m,+1/2}^j(\cos \theta)$ and requiring that our solutions be eigenfunctions of P with eigenvalue ϵ , we see that $a_r = i \epsilon b_r (-1)^{r+1-m}$. Consequently the three-term matrix recurrence relations satisfied by the vector $\begin{bmatrix} a_r \\ b_r \end{bmatrix}$ become a single three-term recurrence relation:¹²

$$\begin{aligned} & a(\epsilon_r \sigma - m_e) \frac{h(r,m)}{r(2r-1)} b_{r-1} \\ & - a(\epsilon_r \sigma + m_e) \frac{h(r+1,m)}{(r+1)(2r+3)} b_{r+1} \\ & + \left[\lambda - \frac{amm_e}{2r(r+1)} \right. \\ & \left. + \epsilon_r \left(r + \frac{1}{2} + a\sigma m \frac{r+\frac{1}{2}}{r(r+1)} \right) \right] b_r = 0, \tag{1.16} \end{aligned}$$

where $h(j,m) = \sqrt{(r^2 - m^2)(r^2 - 1/4)}$ and $\epsilon_r = (-1)^r \epsilon$.

The expressions for the coefficients b_r can be calculated iteratively using the recurrence formula, expressing the eigenvalue λ in the form $\lambda = \sum_{r=0}^{\infty} \lambda_r a^r$ and using the expansion $b_{j\pm r}/b_j = \sum_{k=r}^{\infty} A^{\pm r} a^k, j=0,1,2,3,\dots$. The first few terms in these series are

$$\begin{aligned} \lambda_0 &= -\frac{\epsilon(2j+1)}{2}, \\ \lambda_1 &= -\frac{m(\epsilon\sigma(2j+1) - m_e)}{2j(j+1)}, \\ \lambda_2 &= -\frac{2\epsilon}{(2j+1)^2} \left[\frac{(\epsilon\sigma - m_e)^2 h^2(j,m)}{j^2(2j-1)} \right. \\ & \quad \left. + \frac{(\epsilon\sigma + m_e)^2 h^2(j+1,m)^2}{(j+1)^2(2j+3)} \right], \tag{1.17} \\ \lambda_3 &= -\frac{4(\epsilon\sigma - m_e)^2 h^2(j,m)}{j^2(2j-1)(2j+1)^3} \left[\frac{m(-m_e + \sigma\epsilon)}{(j-1)j(j+1)} \right. \\ & \quad \left. - \frac{2\epsilon\sigma m j}{(j-1)(j+1)} \right] \\ & \quad - \frac{4(\epsilon\sigma + m_e)^2 h^2(j+1,m)}{(j+1)^2(2j+3)(2j+1)^3} \\ & \quad \times \left[-\frac{m(m_e + \sigma\epsilon)}{j(j+1)(j+2)} + \frac{2\epsilon\sigma m(j+1)}{j(j+2)} \right], \end{aligned}$$

for the expansion of the eigenvalue λ , and

$$\begin{aligned} A_1^1 &= -\frac{2\epsilon(m_e - \sigma\epsilon)h(j+1,m)}{(2j+1)^2(j+1)}, \\ A_1^{-1} &= \frac{h(j,m)(\epsilon\sigma - m_e)}{2\epsilon j(2j+1)}, \end{aligned}$$

$$A_2^2 = \frac{h(j+1, m)h(j+2, m)(\sigma^2 - m_e^2)}{(j+1)(j+2)(2j+3)(2j+1)^2}, \quad (1.18)$$

$$A_2^{-2} = \frac{h(j-1, m)h(j, m)(\sigma^2 - m_e^2)}{j(j-1)(2j-1)(2j+1)^2},$$

$$A_2^1 = \frac{4(\epsilon\sigma + m_e)h(j+1, m)}{(j+1)(2j+1)^3} \left[\frac{2\epsilon\sigma m(j+1)}{j(j+2)} - \frac{m(m_e + \sigma\epsilon)}{j(j+1)(j+2)} \right],$$

$$A_2^{-1} = \frac{4(\epsilon\sigma - m_e)h(j, m)}{(j+1)(2j+1)^3} \left[\frac{m(-m_e + \epsilon\sigma)}{(j-1)j(j+1)} - \frac{2\epsilon\sigma mj}{(j-1)(j+1)} \right],$$

where $\epsilon = (-1)^{j-m+1}$.

To justify the preceding perturbation computation we note that the eigenvalue equation can be written in the form $LS = \lambda S$, $L = L_0 + aV$, where

$$L_0 = \begin{bmatrix} 0 & -\frac{\partial}{\partial\theta} - \frac{m}{\sin\theta} - \frac{\cot\theta}{2} \\ \frac{\partial}{\partial\theta} - \frac{m}{\sin\theta} + \frac{\cot\theta}{2} & 0 \end{bmatrix}, \quad (1.19)$$

$$V = \begin{bmatrix} -m_e \cos\theta & -\sigma \sin\theta \\ -\sigma \sin\theta & +m_e \cos\theta \end{bmatrix}, \quad (1.20)$$

$$S = \begin{bmatrix} S_{-1/2} \\ S_{+1/2} \end{bmatrix}, \quad \sigma^2 - m_e^2 > 0.$$

The boundary conditions are (1.15). The inner product is

$$(T, S) = \int_0^\pi (T_{1/2}^* S_{1/2} + T_{-1/2}^* S_{-1/2}) \sin\theta \, d\theta. \quad (1.21)$$

We restrict the argument that follows to the case when $\epsilon = (-1)^{j-m}$; the case when $\epsilon = (-1)^{j-m+1}$ can be treated similarly. It is easy to verify that L is formally self-adjoint with respect to the inner product. Moreover, the operator L_0 on this space is self-adjoint with discrete spectrum

$$L_0 S_j^0 = \mu_j S_j^0, \quad \mu_j = -j - \frac{1}{2}; \quad j=0, 1, 2, \dots \quad (1.22)$$

Thus the eigenvalue decomposition for the resolvent operator $(L_0 - \lambda I)^{-1}$ takes the form

$$(L_0 - \lambda I)^{-1} S_j^0 = \frac{-1}{j + \lambda + \frac{1}{2}} S_j^0, \quad j=0, 1, 2, \dots \quad (1.23)$$

It follows that $(L_0 - \lambda I)^{-1}$ is a compact self-adjoint operator for real λ not in the spectrum of L_0 . The perturbing operator V is bounded and self-adjoint with operator norm $\|V\| = \sigma$. From the identity

$$(L - \lambda I)^{-1} = (L_0 - \lambda I)^{-1} - a(L_0 - \lambda I)^{-1} V (L - \lambda I)^{-1} \quad (1.24)$$

and the facts that (i) the product of a compact operator and a bounded operator is compact, and (ii) the sum of two compact operators is compact, it follows that the resolvent operator $(L - \lambda I)^{-1}$ is self-adjoint and compact for real λ not in the spectrum. Thus L can be defined uniquely as a self-adjoint operator with discrete spectrum.¹³ It is easy to check that the spectrum is of multiplicity 1. It follows from Chap. VII of Ref. 13 that $L = L_0 + aV$ is a so-called “self-adjoint holomorphic family of type (A)” defined for all real a . The radius of convergence for each power series expansion of the perturbed eigenvalues and eigenfunctions about $a=0$ is at least $1/(2\sigma)$ in the complex a plane. Moreover, the eigenfunctions found from the perturbation process from a Hilbert space basis for all real a .

For large a the asymptotic form of the eigenvalues and eigenfunctions can be computed. In order to do this we look for solutions of the form

$$S_{\pm 1/2} = e^{a\phi(\cos\theta)} \psi_{\pm 1/2}(\theta) \left(1 + \frac{f_1^\pm(\theta)}{a} + \frac{f_2^\pm(\theta)}{a^2} + \dots \right),$$

$$\lambda = a\mu + \lambda_0 + \frac{\lambda_1}{a} + \frac{\lambda_2}{a^2} + \dots \quad (1.25)$$

Equating powers of a we find the leading order condition

$$\phi'^2 + \mu^2 - \sigma^2 + (\sigma^2 - m_e^2) \cos^2\theta = 0. \quad (1.26)$$

In order to obtain a single-valued expression for ϕ we choose $\mu = m_e$ for which $\phi = \pm \sqrt{\sigma^2 - m_e^2} \times \cos\theta = \beta \cos\theta$, and the condition

$$m_e(1 + \cos\theta) \psi_{1/2} = (\beta - \sigma) \sin\theta \psi_{-1/2}. \quad (1.27)$$

Further conditions can be solved to give

$$\psi_{-1/2} = m_e (\sin(\theta/2))^{-n-1} (\cos(\theta/2))^n,$$

$$\psi_{1/2} = (\beta - \sigma) (\sin(\theta/2))^{-n} (\cos(\theta/2))^{n-1}, \quad (1.28)$$

and

$$2\lambda_0 m_e - (2m + 1)\sigma = \beta n, \tag{1.29}$$

where the integer $n = j - \frac{1}{2}[|m - \frac{1}{2}| + |m + \frac{1}{2}|]$.

The functions f_1^\pm are given by

$$f_1^- = A \frac{\sin(\theta/2)}{\cos^3(\theta/2)} + B \tan \frac{\theta}{2} + C \sec^2 \frac{\theta}{2} + D \csc^2 \frac{\theta}{2} + E \cot \theta + F \csc \theta + G \sec \frac{\theta}{2} + H \sec \theta, \tag{1.30}$$

$$f_2^+ = -f_1^- \frac{(n + m + \frac{1}{2})}{(\beta - \sigma)\sin^2 \theta} - \frac{\lambda_0}{2m_e \cos^2(\theta/2)},$$

where

$$A = -\frac{m_e n(2m - 1)}{6\beta}, \quad B = -\frac{2m_e n(m + 1)}{3\beta},$$

$$C = -\frac{\lambda_0(\sigma + \beta)(n + \frac{1}{2})}{8\beta m_e} - \frac{\lambda_0(\sigma - \beta)(m - \frac{1}{2})}{4\beta m_e} + \frac{\lambda_0^2}{4\beta^2}$$

$$D = \frac{n(n + 2)}{16\beta},$$

$$E = -\frac{m_e m(n + 1)}{4\beta}, \quad F = -\frac{m_3(n + 1)}{8\beta},$$

$$G = \frac{(n - 3)}{2\beta} \left[\frac{n}{4} + \frac{\lambda_0(\beta - \sigma)}{2m_e} \right], \quad H = -\frac{(m + \frac{1}{2})(n - 3)}{8\beta}.$$

The next term in the asymptotic series for the eigenvalue λ is given by

$$\lambda_1 m_e = -\frac{\lambda_0}{4m_e} \left[\left(\frac{7}{2} + 2n + 2m \right) \sigma + \left(\frac{3}{2} - 2m \right) \beta \right] - \frac{(n^2 + n/2 - 1 - 3mn)}{16}. \tag{1.31}$$

The higher-order terms in the asymptotic series become increasingly complex. The next term is given by

$$\begin{aligned} \lambda_2 m_e = & \left[-\frac{\lambda_1(2m + 2n + 1)\beta}{4m_e} + \frac{\lambda_0^2(\sigma + \beta)(2m + 2n + 1)}{16m_e^2} + \frac{\lambda_0^2 n(\beta - \sigma)}{8m_e^2} + \frac{(3n - 1)(2m + 2n + 1)}{32m_e} \right. \\ & \left. - \frac{\lambda_1 n(\beta - \sigma)}{4m_e} \right] + \frac{1}{32} \left[2n(n + 2) + \left(m + \frac{1}{2} \right)(n + 1) \right] \left[-\frac{(\beta - \sigma)(8\beta\lambda_1 + (1 - 2n)\lambda_0)}{16m_e} - \frac{\lambda_0^2}{8} \right. \\ & \left. + \frac{\lambda_0(\sigma + \beta)(2m + 3)}{m_e} - \frac{1}{128} (6m + 7 - 2n)(2m + 1 - 2n) \right] + \frac{(n - 3)}{2} \left[\frac{n}{4} + \frac{\lambda_0}{2m_e} (\beta - \sigma) \right] \\ & \times \left[\frac{\lambda_0(\sigma + \beta)(2m + n + 1)}{\beta m_e} + \frac{\lambda_1 m_3}{\beta} + \frac{\lambda_0 n(\beta - \sigma)}{\beta m_e} \frac{1}{64} (10m + 2n + 1)(2m - 2n + 1) \right] \\ & + \frac{\lambda_0(\beta - \sigma)}{16} (n + 1)(2m + 1) - \left[\frac{\lambda_0(\sigma + \beta)(n + \frac{1}{2})}{m_e} + \frac{\lambda_0(\sigma - \beta)(m - \frac{1}{2})}{m_e} - \frac{\lambda_0^2}{4} + \frac{(m + \frac{1}{2})(n + 1)}{32} \right] \\ & \times \left[\frac{\lambda_0(\sigma + \beta)(2m + 2n + 1)}{m_e} + \frac{\lambda_1 m_e}{\beta} + \frac{\lambda_0 n(\beta - \sigma)}{4\beta m_e} + \frac{1}{32\beta} (2n + 6m - 1) \right. \\ & \left. \times (2n - 2m - 1) \right] - \frac{(m + \frac{1}{2})(n - 3)}{8} \left[\frac{\lambda_0(\sigma + \beta)(2m + 2n + 1)}{8\beta m_e} + \frac{\lambda_1 m_e}{\beta} + \frac{\lambda_0 n(\beta - \sigma)}{4\beta m_e} \right. \\ & \left. - \frac{1}{8\beta} (2m - 2n + 1)(n + 2m - 1) \right]. \tag{1.32} \end{aligned}$$

To obtain the connection with the functions that are eigenfunctions of P we need only take suitable combinations of the two independent functions whose asymptotic properties we have computed here. The second solution can be obtained by taking the transformation $\theta \rightarrow \pi - \theta$.

II. THE FUNCTIONS $R_{\pm 1/2}$ AND THEIR PROPERTIES

The coupled equations for the functions $R_{\pm 1/2}$ can be solved by methods similar to those adopted for the θ -dependent functions $S_{\pm 1/2}$. Choosing new functions V_{\pm} defined according to

$$V_+ = \Delta^{1/2} R_{+1/2}, \quad V_- = R_{-1/2} \tag{2.1}$$

and a new variable A defined by

$$r - M = \sqrt{a^2 + e^2 - M^2} \sinh A \tag{2.2}$$

we can write these equations as

$$\left[\frac{\partial}{\partial A} + R \cosh A + \left(S + \frac{1}{2} \right) \tanh A + \frac{T}{\cosh A} \right] V_- = (\lambda + im_e(M + \sqrt{a^2 + e^2 - M^2} \sinh A)) V_+, \tag{2.3}$$

$$\left[\frac{\partial}{\partial A} - R \cosh A - \left(S - \frac{1}{2} \right) \tanh A - \frac{T}{\cosh A} \right] V_+ = (\lambda - im_e(M + \sqrt{a^2 + e^2 - M^2} \sinh A)) V_-,$$

where $R = i\sigma\sqrt{a^2 + e^2 - M^2}$, $S = 2i\sigma M - ie/\sqrt{2}$, and

$$T = \frac{i[\sigma(2M^2 - e^2) + am] - ieM/\sqrt{2}}{\sqrt{a^2 + e^2 - M^2}}. \tag{2.4}$$

Solutions of these equations can be sought in the form

$$V_+ = \sum_r B_r U_{\rho\eta+1/2}^{\nu+r}, \tag{2.5}$$

$$V_- = \sum_r A_r U_{\rho\mu+1/2}^{\nu+r},$$

where $\rho = iT$ and $\eta = -S$.

The functions $U_{\mu,\epsilon}^\alpha$ are analytic continuations of the matrix elements of the rotation group, viz., $U_{\mu,\epsilon}^\alpha = u_{\mu,\epsilon}^\alpha(i \sinh A)$. These functions satisfy the recurrence relations induced from the rotation group matrix elements. This can be seen by invoking the relations given by Gelfand *et al.*¹¹ for the rotation group in their complexified form. Typically such relations are

$$\left[\frac{\partial}{\partial A} - \frac{(i\rho + (\eta + \frac{1}{2}) \sinh A)}{\cosh A} \right] U_{\rho\eta+1/2}^{\nu+r} = -\sqrt{(\nu+r+\frac{1}{2})^2 - \eta^2} U_{\rho\eta-1/2}^{\nu+r},$$

$$\left[\frac{\partial}{\partial A} + \frac{(i\rho + (\eta - \frac{1}{2}) \sinh A)}{\cosh A} \right] U_{\rho\eta-1/2}^{\nu+r} = -\sqrt{(\nu+r+\frac{1}{2})^2 - \eta^2} U_{\rho\eta+1/2}^{\nu+r}. \tag{2.6}$$

Consequently, we obtain the recurrence relations

$$\left[-\lambda - im_e M + \frac{m_e \sqrt{a^2 + e^2 - M^2} \rho (\eta - \frac{1}{2})}{(\nu+r)(\nu+r+1)} \right] A_r - m_e \sqrt{a^2 + e^2 - M^2} \left[\frac{\sqrt{[(\nu+r)^2 - \rho^2][(\nu+r)^2 - (\eta - \frac{1}{2})^2]}}{(2(\nu+r) - 1)(\nu+r)} A_{r-1} \right. \\ \left. + \frac{\sqrt{[(\nu+r+1)^2 - \rho^2][(\nu+r+1)^2 - (\eta - \frac{1}{2})^2]}}{(\nu+r+1)(2(\nu+r) + 3)} A_{r+1} \right] \\ = - \left[\sqrt{\left(\nu+r+\frac{1}{2} \right)^2 - \eta^2} + iR \frac{\sqrt{(\nu+r+\frac{1}{2})^2 - \eta^2} \rho}{(\nu+r+1)(\nu+r)} \right] B_r + iR \left[\frac{\sqrt{[(\nu+r-\eta)^2 - \frac{1}{4}][(\nu+r)^2 - \rho^2]}}{(\nu+r)(2(\nu+r) - 1)} B_{r-1} \right. \\ \left. - \frac{\sqrt{[(\nu+r+\eta+1)^2 - \frac{1}{4}][(\nu+r)^2 - \rho^2]}}{(\nu+r+1)(2(\nu+r) + 3)} B_{r+1} \right]. \tag{2.7}$$

$$\begin{aligned}
 & \left[\lambda - im_e M + \frac{m_e \sqrt{a^2 + e^2 - M^2} \rho (\eta + \frac{1}{2})}{(\nu + r)(\nu + r + 1)} \right] B_r + m_e \sqrt{a^2 + e^2 - M^2} \left[\frac{\sqrt{[(\nu + r)^2 - \rho^2][(\nu + r)^2 - (\eta + \frac{1}{2})^2]}}{(\nu + r)(2(\nu + r) - 1)} B_{r-1} \right. \\
 & \quad \left. + \frac{\sqrt{[(\nu + r + 1)^2 - \rho^2][(\nu + r + 1)^2 - (\eta + \frac{1}{2})^2]}}{(\nu + r + 1)(2(\nu + r) + 3)} B_{r+1} \right] \\
 & = - \left[\sqrt{\left(\nu + r + \frac{1}{2}\right)^2 - \eta^2} + iR \frac{\sqrt{(\nu + r + \frac{1}{2})^2 - \eta^2}}{(\nu + r)(\nu + r + 1)} \right] A_r - \left[\frac{\sqrt{[(\nu + r + \eta)^2 - \frac{1}{4}][(\nu + r)^2 - \rho^2]}}{(\nu + r)(2(\nu + r) - 1)} \right. \\
 & \quad \left. A_{r-1} - \frac{\sqrt{[(\nu + r - \eta + 1)^2 - \frac{1}{4}][(\nu + r)^2 - \rho^2]}}{(\nu + r)(2(\nu + r) + 1)} A_{r+1} \right]. \tag{2.8}
 \end{aligned}$$

These relations are of the same type as derived for the functions $S_{\pm 1/2}$ with recurrence relations of the form

$$\zeta_r Z_{r-1} + \eta_r Z_r + \omega_r Z_{r+1} = 0, \tag{2.9}$$

where

$$Z_r = \begin{bmatrix} A_r \\ B_r \end{bmatrix}.$$

For large a representations of the solutions can be achieved as follows. The expansion of the eigenvalue λ takes the form

$$\lambda = am_e + \lambda_0 + \frac{\lambda_1}{a} + \frac{\lambda_2}{a^2} + \frac{\lambda_3}{a^3} + \dots \tag{2.10}$$

For large a we seek solutions

$$V_{\pm} = \psi_{\pm} e^{\beta r} \left[1 + \frac{f_1^{\pm}(r)}{a} + \frac{f_2^{\pm}(r)}{a^2} + \frac{f_3^{\pm}(r)}{a^3} + \dots \right]. \tag{2.11}$$

For solutions of this type the constants ψ_{\pm} must satisfy

$$i(\beta + \sigma)\psi_{-} = m_e \psi_{+}, \tag{2.12}$$

where $\beta = \sqrt{\sigma^2 - m_e^2}$.

Without loss of generality we can assume $f_n^{\pm}(r) = \sum_{i=0}^n a_{n,i}^{\pm} r^i$ with $a_{n,0}^{\pm} = 0, n=0,1,2,\dots$. The first few terms in this expansion are

$$\begin{aligned}
 a_{1,0}^{-} &= \frac{2\lambda_0\sigma - (2m+1)m_e}{2m\beta}, \\
 a_{1,1}^{-} &= i(m+1) - \frac{i\lambda_0 m_e}{\beta} + \frac{i(2m+1)m_e^2}{2(\sigma+\beta)\beta}, \tag{2.13}
 \end{aligned}$$

$$\begin{aligned}
 a_{1,1}^{+} &= im \\
 & - \frac{4\lambda_0 m_e \sigma (\sigma - \beta) - (2m+1)m_e^2 (\sigma + \beta) - 2\lambda_0 m_e^3}{\beta(2\sigma(\sigma + \beta) - m_e^2)}.
 \end{aligned}$$

For the functions V_{\pm} an asymptotic expansion with respect to r can be obtained. We search for solutions of the form

$$V_{\pm} = \phi_{\pm} e^{\varphi(r)\rho} \left(1 + \frac{v_1^{\pm}}{r} + \frac{v_2^{\pm}}{r^2} + \frac{v_3^{\pm}}{r^3} + \dots \right) \tag{2.14}$$

for suitable functions $\varphi(r)$, and constants ϕ_{\pm}, ρ . An expansion of this type is possible if

$$\begin{aligned}
 (\beta + \sigma)\phi_{-} &= m_e \phi_{+}, \\
 \rho &= -\sigma ie / \sqrt{2}\beta + iM(2\beta + m_e^2/\beta). \tag{2.15}
 \end{aligned}$$

The first nonzero terms of this expansion are given by the coefficients

$$\begin{aligned}
 v_1^{-} &= -M - i\lambda/m_e \\
 v_2^{+} &= -e / \sqrt{2}\beta + m_e^2 M / \beta(\beta + \sigma). \tag{2.16}
 \end{aligned}$$

In the case of flat space, i.e., $e=M=0$, it is possible to expand one set of complete eigenfunctions of the Dirac

equation in terms of another. For the Dirac equation this is achieved using the Majorana representation of the Dirac gamma matrices, viz.,

$$\gamma = \begin{bmatrix} \mathbf{0} & -\sigma \\ \sigma & \mathbf{0} \end{bmatrix}, \quad \gamma^5 = \begin{bmatrix} -\mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix}, \quad \gamma^0 = \begin{bmatrix} \mathbf{0} & \mathbf{I} \\ \mathbf{I} & \mathbf{0} \end{bmatrix}. \tag{2.17}$$

From our knowledge of the separation of variables in oblate coordinates (i.e., inserting the conditions $e=M=0$) the separable solutions are characterized as eigenfunctions of the operator

$$Q = \gamma^5 \gamma \cdot L + \gamma^1 + a \left(\gamma^5 \gamma^1 \frac{\partial}{\partial z^2} + \gamma^5 \gamma^0 \frac{\partial}{\partial z^3} \right), \tag{2.18}$$

where $L_i = \epsilon_{ijk} z^j \partial / \partial z^k, i=1,2,3$.

We now look for solutions of the eigenvalue equation $Q\Psi = \lambda\Psi$ that are also solutions of the Dirac equation:

$$i\gamma^\mu \frac{\partial}{\partial z^\mu} \psi = m_e \psi. \tag{2.19}$$

Here $z^\mu, \mu = 0,1,2,3$, are Cartesian coordinates in Minkowski space-time. If a standard choice of spherical coordinates is made, i.e., $z^0 = t, z^1 = \omega \sin \alpha \cos \gamma, z^2 = \omega \sin \alpha \sin \gamma, z^3 = \omega \cos \alpha$, and a formal Fourier transform

$$f\psi = \int \exp(ik^0 z^0 + i\mathbf{k} \cdot \mathbf{z}) \psi dz^0 dz$$

taken with $k^0 = \sigma$,

$$\mathbf{k} = (k^1, k^2, k^3) = \sqrt{\sigma^2 - m_e^2} (\sin \theta \cos \varphi, \sin \theta \sin \varphi, \cos \theta),$$

and $d\mathbf{x} = \sin \alpha d\alpha d\gamma$ these two conditions are equivalent to the four equations

$$\begin{aligned} & \left[\frac{\partial}{\partial \theta} - \frac{im}{\sin \theta} \frac{\partial}{\partial \varphi} + \frac{\cot \theta}{2} + \sigma a \sin \theta \right] f\bar{\psi}_4 \\ & = -(\lambda - am_e \cos \theta) f\bar{\psi}_1, \\ & \left[\frac{\partial}{\partial \theta} + \frac{im}{\sin \theta} \frac{\partial}{\partial \varphi} + \frac{\cot \theta}{2} - \sigma a \sin \theta \right] f\bar{\psi}_3 \\ & = (\lambda - am_e \cos \theta) f\bar{\psi}_2, \end{aligned} \tag{2.20}$$

$$\begin{aligned} & \left[\frac{\partial}{\partial \theta} + \frac{im}{\sin \theta} \frac{\partial}{\partial \varphi} + \frac{\cot \theta}{2} - \sigma a \sin \theta \right] f\bar{\psi}_1 \\ & = (\lambda - am_e \cos \theta) f\bar{\psi}_4, \\ & \left[\frac{\partial}{\partial \theta} - \frac{im}{\sin \theta} \frac{\partial}{\partial \varphi} + \frac{\cot \theta}{2} + \sigma a \sin \theta \right] f\bar{\psi}_2 \\ & = -(\lambda - am_e \cos \theta) f\bar{\psi}_3, \end{aligned}$$

where $f\psi = R_1(-\theta)R_3(-\varphi)f\bar{\psi}$ and R_1, R_3 are rotations about the indicated coordinate axes in three-space.

The solutions of the eigenvalue equations in the transformed space of Dirac spinors $f\Psi$ are of the form

$$\begin{aligned} f\bar{\psi}_1 &= (\beta - i\sigma) S_{-1/2}(\theta) e^{i(\sigma t + m\varphi)}, \\ f\bar{\psi}_2 &= im_e S_{1/2}(\theta) e^{i(\sigma t + m\varphi)}, \\ f\bar{\psi}_3 &= im_e S_{-1/2}(\theta) e^{i(\sigma t + m\varphi)}, \\ f\bar{\psi}_4 &= (\beta - i\sigma) S_{1/2}(\theta) e^{i(\sigma t + m\varphi)}. \end{aligned} \tag{2.21}$$

If the solutions are also eigenfunctions of the discrete transformation P then the functions $S_{\pm 1/2}$ appearing in these expressions are just those we have already studied. The basic idea is the following. From the expressions for $f\bar{\psi}$ recover the expressions for $f\psi$. Using the expansion of the function $e^{i\mathbf{k} \cdot \mathbf{x}}$ in terms of spherical Bessel functions, as for instance found in Ref. 14, the form of ψ is recovered. The Dirac spinors that result are eigenfunctions of Q and P , are solutions of Dirac's equation, and are represented relative to the Cartesian coordinate and spin frames given in the definition above. Then, transforming the spinor basis used in oblate spheroidal coordinates, we obtain expressions for solutions of the Dirac equation, in terms of series of spherical Bessel functions, that are eigenfunctions of Q and P . The expressions for the components are given by

$$\begin{aligned} \psi_1 &= \sum_{L=0}^{\infty} \sum_{r=0}^{\infty} [(\beta - i\sigma) b_r C(\frac{1}{2}, -\frac{1}{2}; r, m | L, K) \\ & \quad \times C(\frac{1}{2}, -\frac{1}{2}; r, \frac{1}{2} | L, 0) - m_e a_r C(\frac{1}{2}, -\frac{1}{2}; r, m | L, K) \\ & \quad \times C(\frac{1}{2}, -\frac{1}{2}; r, -\frac{1}{2} | L, 0)] \\ & \quad \times i^L j_L(\beta r) u_{m-1/2}^L(\cos \alpha) e^{i(m-1/2)\gamma}, \end{aligned}$$

$$\begin{aligned} \psi_2 = & \sum_{L=0}^{\infty} \sum_{r=0}^{\infty} [i(\beta - i\sigma)b, C(\frac{1}{2}, \frac{1}{2}; r, m | L, K) \\ & \times C(\frac{1}{2}, -\frac{1}{2}; r, \frac{1}{2} | L, 0) \\ & + im_e a, C(\frac{1}{2}, \frac{1}{2}; r, m | L, K) C(\frac{1}{2}, \frac{1}{2}; r, -\frac{1}{2} | L, 0)] \\ & \times i^L j_L(\beta r) u_{m+1/2} (\cos \alpha) e^{i(m+1/2)\gamma}, \end{aligned} \quad (2.22)$$

where $C(j, m; l, n | L, M)$ are the Clebsch–Gordan coefficients of the rotation group. The expressions for ψ_3 and ψ_4 can be obtained by interchanging the expressions $(\beta - i\sigma)$ and im_e in the expressions for ψ_1 and ψ_2 to obtain ψ_3 and ψ_4 , respectively. The change in spin frame from Cartesian coordinates to the frame specified by the null tetrad given above can be readily computed. We standardize the choice of oblate coordinates as $z^0 = t$, $z^1 = \sqrt{r^2 + a^2} \sin \alpha \cos \gamma$, $z^2 = \sqrt{r^2 + a^2} \sin \alpha \sin \gamma$, and $z^3 = r \cos \alpha$. The Lorentz transformation that maps the vector fields $D^\mu = \partial/\partial z^\mu$ into the vector fields

$$\begin{aligned} D^0 &= \frac{1}{\sqrt{2}}(l^\mu + n^\mu) \frac{\partial}{\partial z^\mu}, \\ D^1 &= \frac{1}{\sqrt{2}}(l^\mu - n^\mu) \frac{\partial}{\partial z^\mu}, \\ D^2 &= \frac{1}{\sqrt{2}}(m^\mu + \bar{m}^\mu) \frac{\partial}{\partial z^\mu}, \\ D^3 &= \frac{1}{\sqrt{2}}(m^\mu - \bar{m}^\mu) \frac{\partial}{\partial z^\mu}, \end{aligned} \quad (2.23)$$

according to $D^\mu = L^\mu_\nu D^\nu$ can readily be calculated. The matrix elements L^μ_ν are given by

$$\begin{aligned} L^0_0 &= \frac{1}{\sqrt{2}} \left[1 + \frac{(r^2 + a^2)}{\rho^2} \right], \\ L^0_1 &= \frac{1}{\sqrt{2}} \left[r \sin \alpha \cos \gamma \left[\frac{1}{\sqrt{r^2 + a^2}} - \frac{\sqrt{r^2 + a^2}}{\rho^2} \right] \right. \\ & \quad \left. + a \sin \alpha \sin \gamma \left[\frac{-1}{\sqrt{r^2 + a^2}} - \frac{\sqrt{r^2 + a^2}}{\rho^2} \right] \right], \\ L^0_2 &= \frac{1}{\sqrt{2}} \left[r \sin \alpha \sin \gamma \left[\frac{1}{\sqrt{r^2 + a^2}} - \frac{\sqrt{r^2 + a^2}}{\rho^2} \right] \right. \\ & \quad \left. + a \sin \alpha \cos \gamma \left[\frac{1}{\sqrt{r^2 + a^2}} + \frac{\sqrt{r^2 + a^2}}{\rho^2} \right] \right], \end{aligned} \quad (2.24)$$

$$\begin{aligned} L^0_3 &= \frac{1}{\sqrt{2}} \cos \alpha \left[1 - \frac{r^2 + a^2}{\rho^2} \right], \\ L^1_0 &= \frac{-1}{\sqrt{2}} ia \sin \alpha \left[\frac{1}{\rho} + \frac{1}{\rho^*} \right], \\ L^1_1 &= \frac{1}{\sqrt{2}} \left[i\sqrt{r^2 + a^2} \cos \alpha \cos \gamma \left[\frac{1}{\rho} - \frac{1}{\rho^*} \right] \right. \\ & \quad \left. - \sqrt{r^2 + a^2} \sin \gamma \left[\frac{1}{\rho} + \frac{1}{\rho^*} \right] \right], \\ L^1_2 &= \frac{1}{\sqrt{2}} \left[i\sqrt{r^2 + a^2} \cos \alpha \sin \gamma \left[\frac{1}{\rho} - \frac{1}{\rho^*} \right] \right. \\ & \quad \left. + \sqrt{r^2 + a^2} \cos \gamma \left[\frac{1}{\rho} - \frac{1}{\rho^*} \right] \right], \\ L^1_3 &= \frac{1}{\sqrt{2}} r \sin \alpha \left[\frac{1}{\rho} - \frac{1}{\rho^*} \right], \\ L^2_0 &= \frac{1}{\sqrt{2}} ia \sin \alpha \left[\frac{1}{\rho} - \frac{1}{\rho^*} \right], \\ L^2_1 &= \frac{1}{\sqrt{2}} \left[\sqrt{r^2 + a^2} \cos \alpha \cos \gamma \left[\frac{1}{\rho} + \frac{1}{\rho^*} \right] \right. \\ & \quad \left. + \sqrt{r^2 + a^2} i \sin \gamma \left[\frac{1}{\rho} + \frac{1}{\rho^*} \right] \right], \\ L^2_2 &= \frac{1}{\sqrt{2}} \left[\sqrt{r^2 + a^2} \cos \alpha \sin \gamma \left[\frac{1}{\rho} + \frac{1}{\rho^*} \right] \right. \\ & \quad \left. - i\sqrt{r^2 + a^2} \cos \gamma \left[\frac{1}{\rho} - \frac{1}{\rho^*} \right] \right], \\ L^2_3 &= \frac{1}{\sqrt{2}} r \sin \alpha \left[\frac{1}{\rho} - \frac{1}{\rho^*} \right], \\ L^3_0 &= \frac{1}{\sqrt{2}} \left[1 - \frac{(r^2 + a^2)}{\rho^2} \right], \\ L^3_1 &= \frac{1}{\sqrt{2}} \left[r \sin \alpha \cos \gamma \left[\frac{1}{\sqrt{r^2 + a^2}} - \frac{\sqrt{r^2 + a^2}}{\rho^2} \right] \right. \\ & \quad \left. + a \sin \alpha \sin \gamma \left[\frac{-1}{\sqrt{r^2 + a^2}} + \frac{\sqrt{r^2 + a^2}}{\rho^2} \right] \right] \end{aligned}$$

$$L^3_2 = \frac{1}{\sqrt{2}} \left[r \sin \alpha \sin \gamma \left[\frac{1}{\sqrt{r^2 + a^2}} + \frac{\sqrt{r^2 + a^2}}{\rho^2} \right] + a \sin \alpha \cos \gamma \left[\frac{1}{\sqrt{r^2 + a^2}} - \frac{\sqrt{r^2 + a^2}}{\rho^2} \right] \right]$$

$$L^3_3 = \frac{1}{\sqrt{2}} \cos \alpha \left[1 + \frac{(r^2 + a^2)}{\rho^2} \right].$$

The solutions of Dirac’s equation, relative to the frame (1.2), denoted by

$${}_0\psi = \begin{bmatrix} \phi_A \\ \chi_{B'} \end{bmatrix}$$

are obtained by applying $\Lambda(r, \alpha, \gamma)$, the representative of $L(r, \alpha, \gamma)$ acting on the Dirac spinors Ψ . However, these are just the solutions of Dirac’s equation found in terms of Teukolsky functions above. What has been achieved here is expressions for these solutions in terms of sums of spherical Bessel functions and spherical harmonics. Clearly these expressions will, in general, be quite complex. We content ourselves with the derivation of an expansion formula for the functions $R_{\pm 1/2}$. Indeed if we take $\alpha = \theta = \pi/2$, $\omega = \sqrt{r^2 + a^2}$, then L can be factored in the form $R_3(\varphi)N_1(A)R_3(\delta)$ where

$$e^A = 1 + \frac{a^2}{2r^2} + \frac{a}{r} \left[1 + \frac{a^2}{4r^2} \right]^{1/2},$$

$$e^{i\delta} = i \left[\frac{(r + ia)(r + ia/2)}{(r - ia)(r - ia/2)} \right]^{1/2}.$$

The corresponding transformation matrix acting on the Dirac spinor then has the form $\Lambda(r, \pi/2, \gamma) = e^{\gamma^1 \gamma^2 \varphi/2} e^{\gamma^0 \gamma^1 A/2} e^{\gamma^1 \gamma^2 \delta/2}$ and, consequently, ${}_0\psi = \Lambda(r, \pi/2, \gamma)\psi$.

The small a expansion of $P_{\pm} = V_+ \pm V_-$ can be expressed in terms of Bessel functions. The first few terms in the expressions are

$$P_+ = (\sigma + m_3)^{1/2} J_j(\beta r) r^{1/2} - \frac{am}{2(j+1)}$$

$$\times (\sigma - m_e)^{1/2} J_{j+1}(\beta r) r^{-1/2} + \frac{a\beta(\sigma + m_e)^{1/2}}{16j^2}$$

$$\times [j(j+1) + 2m^2] J_{j-1}(\beta r) r^{-1/2} + \dots, \quad (2.25)$$

$$P_- = (m_e - \sigma)^{1/2} J_{j+1}(\beta r) r^{1/2}$$

$$+ iam \frac{(\sigma + m_e)^{1/2}}{2j} J_j(\beta r) r^{-1/2}$$

$$+ \frac{a^2 \beta (m_e - \sigma)^{1/2}}{16(j+1)^2} [(j+2)(j+1)$$

$$- 2m^2] J_{j+2}(\beta r) r^{-1/2} + \dots.$$

An interesting application of these solutions would be the solution of the MIT bag model of confinement for which the boundary is the surface of an oblate spheroid. For this problem the appropriate boundary condition is

$$i\gamma^\mu n_\mu \psi = \psi \quad \text{for } r=r_0, \quad (2.26)$$

where $n^\mu n_\mu = -1$ and $r = r_0$ is the surface of the spheroidal bag. In the tetrad formalism the nonzero components of the unit normal spacelike vector n_μ are $n_{00} = \sqrt{\rho^2/2\Delta}$, $n_{11} = -\sqrt{\Delta/2\rho^2}$. If we naively apply the boundary conditions to a single solution of the Dirac equation as found in Sec. I this would require that $R_{1/2} = \sqrt{-\bar{\rho}^*/\bar{\rho}\Delta}^{-1/2} R_{-1/2}$ for $r = r_0$, which is clearly impossible. If, however, the boundary conditions are modified so as to be of the form

$$i\gamma^\mu n_\mu \psi = (\cos \alpha + i\gamma^0 \sin \alpha)\psi, \quad (2.27)$$

where $e^{i\alpha} = \sqrt{-\bar{\rho}^*/\bar{\rho}}$, then this boundary value problem can be more readily solved, as it reduces to the requirement that $R_{1/2} = i\Delta^{-1/2} R_{-1/2}$ for $r = r_0$. The boundary conditions (2.27) do not adequately describe a quantum bag although they do imply that the probability density vanishes on the bag surface. In order to solve the bag model conditions a solution must be represented as a sum of eigenfunctions of the type developed above. There are then no problems in principle with the bag boundary conditions. We shall return to this problem subsequently.
